

1. What happens to these 3 clients? Do their connect()s fail, or time out, or succeed?

After initially running `./client localhost` in a separate terminal, these three background clients were unable to connect until I forcibly terminated the first client.

2. Do any other calls block?

The background client requests are frozen until the first client exits.

3. Now let the first client exit. What happens?

The three background clients are now able to quickly connect one by one and promptly send

`"hello server!"` to the server.
